

ABSTRACT OF THE DISCLOSURE

A collapsible open top swing that is free of cross supports between upper side portions of the frame to maximize access to the baby in the swing. The open top swing has a broad base by virtue of the sweeping rear legs, yet the open top swing is collapsible by swinging the rear legs toward the front legs. This swinging takes place at a leg axis that is offset from a swing axis for the swing. The front leg engages a first unit for the leg axis at a first location and engages a second unit for the swing axis at a second location rearwardly and upwardly from the first location to mechanically and visually separate the axis from each other. The front and rear legs are the same length and same shape between their proximal and distal ends to minimize manufacturing costs, yet when in a closed position the distal ends of the rear legs project beyond the distal ends of the front legs.
